Task 1

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
1	Registration accepts a single-character username and password	Enter username a, a valid-format email and a one-character password. Click Sign Up.	Expected: Minimum length validation should prevent registration. Actual: Registration succeeded.	Medium	Minimum length validation may be missing or insufficient.
2	Email ownership is not verified during registration, allowing users to register using email addresses they do not own.	1. Open the Sign-up page. 2. Enter a username, an email address you don't own, and a password. 3. Click Sign up. 4. Observe that registration succeeds without OTP verification. 5. Navigate to the Sign-in page. 6. Enter the same registered email and password. 7. Click Sign in and check whether login is successful without email verification.	Expected: Users should verify their email through OTP before account activation. Unverified accounts should not be allowed to log in. Actual: Registration succeeds without requiring email verification. The sign-in page also does not visibly request OTP verification.	High	Email OTP verification may be missing or not properly implemented in the backend. The authentication system may also lack verification-status checks during login.
3	Article creation accepts all types of input, including spaces and special characters, without proper validation.	1. Open the New Article page. 2. Enter different types of input in the Title, Description, and Body fields. 3. Try entering only spaces in the fields.	Expected: The application should validate all input fields and prevent article creation when invalid or whitespace-only content is entered.	Medium	Input validation is implemented but does not properly handle whitespace-only inputs before submitting the article.

		4. Try entering special characters. 5. Click Publish Article. 6. Observe that the article gets created successfully without proper input validation.	Actual: The application accepts different types of inputs, including spaces and special characters, and creates the article without proper validation.		
4	Edit Article allows updating an article with empty fields and inconsistent title validation.	1. Open an existing article. 2. Click Edit Article. 3. Remove the description, body and tags. 4. Click Update Article and observe that the changes are saved. 5. Open Edit Article again. 6. Remove the article title. 7. Click Update Article and observe the validation error. 8. Click Update Article again. 9. Observe that the application accepts the update.	Expected: The application should validate required fields and prevent saving an article with an empty title or body. Actual: The application allows empty fields to be saved, and title validation behaves inconsistently on repeated submissions.	Medium	Edit Article validation may not be properly enforced, resulting in inconsistent validation during repeated submissions.
5	Read more option is displayed even when the article content is very short.	1. Create an article with a short body containing only one word. 2. Publish the article. 3. Navigate to the Home page. 4. Locate the newly published article.	Expected: Read more should only appear when the article content exceeds the preview limit.	Low	The Read More visibility condition may not properly check the article content length.

		5. Observe that the "Read more" option is displayed despite the short content.	Actual: Read more is displayed even when the article contains very little content.		

Deep Dive: Issue #3 – Article creation accepts all types of input, including spaces and special characters, without proper validation.

What is happening:

The article creation form accepts different types of input, including normal text, special characters, and spaces. Even when all required fields contain only spaces, the application allows the article to be published successfully without meaningful content.

Why is it happening:

Input validation is implemented but does not properly validate the actual content entered by users. The application may be treating whitespace as valid input instead of checking whether the fields contain meaningful content.

How to fix it:

1. Trim leading and trailing spaces before validating input fields.
2. Reject fields containing only spaces and display appropriate validation messages.
3. Validate all required fields before allowing article submission.
4. Apply the same validation on the backend to prevent invalid article creation.
